## graphs

A *graph* is a collection of dots we call *vertices* some of which are connected by curves we call *edges*. The relative location of the dots and the shape of the curves are not relevant, we are only concerned with whether or not a given pair of dots is connected by a curve. Initially, we forbid edges from a vertex to itself and multiple edges between two vertices. If  $G$  is a graph, then  $V(G)$  is its set of vertices and  $E(G)$  its set of edges. We write  $|G|$  for the number of vertices in  $V(G)$  and  $\|G\|$  for the number of edges in  $E(G)$ . Two vertices are *adjacent* if they are connected by an edge. The set of vertices to which  $v$  is adjacent is its *neighborhood*, written  $N(v)$ . For the size of  $v$ 's neighborhood  $|N(v)|$ , we write  $d(v)$ .

## coloring vertices

The entire book concerns one simple task: we want to color the vertices of a given graph so that adjacent vertices receive different colors. With no preferences about what the coloring should look like, this is easy, we just give each vertex a different color. Things get interesting when we ask how few colors we can use. We are definitely going to need at least zero colors and that will only do for the graph with no vertices at all. Given one color, we can handle all graphs with no edges. With two colors, we can do any path and any cycle with an even number of vertices [PICTURE]. But, we can't handle a triangle or any other cycle with an odd number of vertices [PICTURE]. In fact, odd cycles are really the only thing that will prevent us from using two colors. A graph  $H$  is a *subgraph* of a graph  $G$ , written  $H \subseteq G$  if  $V(H) \subseteq V(G)$  and  $E(H) \subseteq E(G)$ . When  $H \subseteq G$ , we say that  $G$  *contains*  $H$ . If  $v \in V(G)$ , then  $G - v$  is the graph we get by removing  $v$  and all edges incident to  $v$  from  $G$ . A graph is  $k$ -colorable if we can color its vertices with (at most)  $k$  colors such that adjacent vertices receive different colors.

subgraph,  $\subseteq$   
contains  
 $k$ -colorable

**THEOREM 1.** *A graph is 2-colorable just in case it contains no odd cycle.*

**PROOF.** A graph containing an odd cycle clearly can't be 2-colored. For the other implication, suppose there is a graph that is not 2-colorable and doesn't contain an odd cycle. Then we may pick such a graph  $G$  with  $|G|$  as small as possible. Surely,  $|G| > 0$ , so we may pick  $v \in V(G)$ . If  $x, y \in N(v)$ , then  $x$  is not adjacent to  $y$  since then  $xyz$  would be an odd cycle. So we can construct a graph  $H$  from  $G$  by removing  $v$  and identifying all of  $N(v)$  to a new vertex  $x_v$ . Any odd cycle in  $H$  would contain  $x_v$  and hence give rise to an odd cycle in  $G$ . So  $H$  contains no odd cycle. Since  $|H| < |G|$ , we can 2-color  $H$ , say with red and blue where  $x_v$  gets colored red. But this gives a 2-coloring of  $G$  by coloring all vertices in  $N(v)$  red and  $v$  blue, a contradiction.  $\square$
