King, Lu and Peng [1] showed that  $\chi_f(G) \leq 4 - \frac{2}{67}$  when  $\Delta(G) \leq 4$  and  $G$  does not contain  $K_4$  or  $C_8^2$ . Moreover, they showed that this bound of  $4 - \frac{2}{67}$  lifts to larger  $\Delta$  by hitting maximum cliques (and a few other structures). Edwards and King improved this bound for  $\Delta \geq 6$  using a probabilistic method, getting an upper bound of  $6 - \frac{2}{45}$  for  $\Delta = 6$ . The goal is to improve these bounds by just improving the  $\Delta = 4$  case.

Here is the basic form of the argument. I am going to loosen the bounds for simplicity. Suppose  $\Delta(G) = 4$  and  $G$  doesn't contain  $K_4$  or  $C_8^2$ . Take a 161-coloring of  $G^4$  and let  $X$  be a color class. In  $G$ , blow up each vertex of  $X$  to  $K_2$ . The resulting graph  $Q$  has  $\Delta(Q) \leq 5$ , where the vertices of degree 5 are exactly the blown-up vertices and their neighbors. So, by our choice of  $X$ , the high vertex subgraph of  $Q$  is the disjoint union of graphs of the form  $K_2 * T$  where  $|T| = 4$  (or  $|T| = 3$  if the blown-up vertex was low, but that case is easier). Call these components of the high vertex subgraph  $H_1, \dots, H_k$ .

**Lemma 0.1.**  *$Q$  is 4-colorable.*

First, let's see what Lemma 0.1 gets us.

**Theorem 0.2.**  $\chi_f(G) \leq 4 - \frac{2}{81}$ .

*Proof.* For each of the 161 color classes of  $G^4$ , Lemma 0.1 gives a 4-coloring of  $G$  where each vertex in  $X$  gets 2 colors. Putting together such colorings for each of the 161 color classes gives a 162-fold coloring of  $G$  from a pot of  $4 * 161$  colors.  $\square$

*Proof of Lemma 0.1.* Suppose not and let  $P$  be a 5-critical subgraph of  $Q$ . Let  $L$  be the low vertex subgraph of  $P$  and  $H$  the high vertex subgraph. Since  $X$  is independent in  $G^4$ , for each  $v \in L$ , there is a  $j$  such that  $N(v) - L \subseteq V(H_j)$ . Note that there may be vertices from some  $H_i$  that are now in  $L$ , if so they must have all their neighbors in  $L$ . Also note that for the blown-up vertices that are still high, all their neighbors are high.

By renumbering if necessary, the components of  $H$  are  $H_1, \dots, H_s$  for some  $s \leq k$ . Say  $H_i = K_2 * T_i$  for each  $i$ . We are going to color the  $K_2$  from each  $H_i$  in such a way that we can complete the coloring on  $L$ . There are 6 subsets of  $[4]$  of size 2, assign one  $\{a, b\}$  to each  $H_i$ , color the  $K_2$  with  $a$  and  $b$  and then color  $T_i$  with  $[4] - \{a, b\}$  so that the color classes are as imbalanced as possible (so if  $T_i$  is  $E_4$ , only one color is used, if  $\alpha(T_i) = 3$ , one color is used on three vertices, the other on one). We will show that there is a way to make such an assignment of 2-sets to the  $H_i$  so that the coloring is completable on  $L$ .

Remember that each low vertex has neighbors in at most one  $H_i$ , for  $v \in V(L)$ , let  $h(v)$  be the  $i$  such that  $v$  has a neighbor in  $H_i$  (or 0 if  $v$  has no high neighbors). Given such an assignment to the  $H_i$ , a component  $A$  of  $L$  is *good* if

1.  $A$  has a noncutvertex  $v$  with at least two high neighbors colored the same; or
2.  $A$  has adjacent noncutvertices  $v, w$  such that  $H_{h(v)}$  and  $H_{h(w)}$  are assigned different 2-sets.

Such a component is good because we can color greedily towards  $v$  or  $v, w$  and finish. Note that if  $A$  has only one vertex, say  $v$ , then it is good for every assignment to the  $H_i$  since  $v$  will always satisfy (1).

Take an assignment of 2-sets to the  $H_i$  giving the maximum number of good components in  $L$ . If every component is good, then we are good. So suppose we have a component  $A$  of  $L$  that is not good.

First, suppose  $A$  has a block  $B$  with adjacent noncutvertices  $v$  and  $w$  such that  $h(v) \neq h(w)$ .
